1 Scope

This document specifies a framework for translation between OCF Devices and other ecosystems, and specifies the behaviour of a translator that exposes servers in non-OCF ecosystem to OCF Clients and/or exposes OCF Servers to clients in non-OCF ecosystem. Translation per specific Device is left to other specification (deep translation). This document provides generic requirements that apply unless overridden by a more specific document.

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

3 Terms, definitions, and abbreviated terms

3.1 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO/IEC 30118-1:2018 and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:
- ISO Online browsing platform: available at https://www.iso.org/obp

3.1.1 Asymmetric Client Bridge

an asymmetric client bridge exposes another ecosystem clients into the OCF ecosystem as Virtual OCF Clients (3.1.20). This is equivalent to exposing OCF Servers (3.1.15) into the other ecosystem. How this is handled in each ecosystem is specified on a per ecosystem basis in this document.

3.1.2 Asymmetric Server Bridge

an asymmetric server bridge exposes another ecosystem devices into the OCF ecosystem as Virtual OCF Servers (3.1.23). How this is handled in each ecosystem is specified on a per ecosystem basis in this document.

3.1.3 Bridged Client

a logical entity that accesses data via a Bridged Protocol (3.1.5). For example, an AllJoyn Consumer application is a Bridged Client.

3.1.4 Bridged Device

Bridged Client (3.1.3) or Bridged Server (3.1.8).

3.1.5 Bridged Protocol

another protocol (e.g., AllJoyn) that is being translated to or from OCF protocols

3.1.6 Bridged Resource

represents an artefact modelled and exposed by a Bridged Protocol (3.1.5), for example an AllJoyn object is a Bridged Resource.

3.1.7 Bridged Resource Type

schema used with a Bridged Protocol (3.1.5), for example AllJoyn Interfaces are Bridged Resource Types.
3.1.8 Bridged Server
logical entity that provides data via a Bridged Protocol (3.1.5), for example an AllJoyn Producer is
a Bridged Server. More than one Bridged Server can exist on the same physical platform.

3.1.9 OCF Bridge Device
OCF Device (3.1.11) that can represent devices that exist on the network but communicate using
a Bridged Protocol (3.1.5) rather than OCF protocols.

3.1.10 OCF Client
logical entity that accesses an OCF Resource (3.1.12) on an OCF Server (3.1.15), which might be
a Virtual OCF Server (3.1.23) exposed by the OCF Bridge Device (3.1.9)

3.1.11 OCF Device
logical entity that assumes one or more OCF roles (OCF Client (3.1.10), OCF Server (3.1.15). More
than one OCF Device can exist on the same physical platform.

3.1.12 OCF Resource
represents an artefact modelled and exposed by the OCF Framework

3.1.13 OCF Resource Property
significant aspect or notion including metadata that is exposed through the OCF Resource (3.1.12)

3.1.14 OCF Resource Type
OCF Resource Property (3.1.13) that represents the data type definition for the OCF Resource
(3.1.12)

3.1.15 OCF Server
logical entity with the role of providing resource state information and allowing remote control of its
resources

3.1.16 Symmetric, Asymmetric Bridging
in symmetric bridging, a bridge device exposes OCF Server(s) (3.1.15) to another ecosystem and
exposes other ecosystem’s server(s) to OCF. In asymmetric bridging, a bridge device exposes
OCF Server(s) (3.1.15) to another ecosystem or exposes another ecosystem’s server(s) to OCF,
but not both.

3.1.17 Translator
OCF Bridge Device (3.1.9) component that is responsible for translating to or from a specific
Bridged Protocol (3.1.5). More than one translator can exist on the same OCF Bridge Device (3.1.9),
for different Bridged Protocols (3.1.5).

3.1.18 Virtual Bridged Client
logical representation of an OCF Client (3.1.10), which an OCF Bridge Device (3.1.9) exposes to
Bridged Servers (3.1.8).
3.1.19 Virtual Bridged Server
logical representation of an OCF Server (3.1.15), which an OCF Bridge Device (3.1.9) exposes to
Bridged Clients (3.1.3).

3.1.20 Virtual OCF Client
logical representation of a Bridged Client (3.1.3), which an OCF Bridge Device (3.1.9) exposes to
OCF Servers (3.1.15)

3.1.21 Virtual OCF Device
Virtual OCF Client (3.1.20) or Virtual OCF Server (3.1.23).

3.1.22 Virtual OCF Resource
logical representation of a Bridged Resource (3.1.6), which an OCF Bridge Device (3.1.9) exposes
to OCF Clients (3.1.10)

3.1.23 Virtual OCF Server
logical representation of a Bridged Server (3.1.8), which an OCF Bridge Device (3.1.9) exposes to
OCF Clients (3.1.10).

3.2.1 CRUDN
Create, Read, Update, Delete, and Notify

3.2.2 CSV
Comma separated value
4 Document conventions and organization

4.1 Conventions

In this document a number of terms, conditions, mechanisms, sequences, parameters, events, states, or similar terms are printed with the first letter of each word in uppercase and the rest lowercase (e.g., Network Architecture). Any lowercase uses of these words have the normal technical English meaning.

4.2 Notation

In this document, features are described as required, recommended, allowed or DEPRECATED as follows:

Required (or shall or mandatory).

– These basic features shall be implemented to comply with OIC Core Architecture. The phrases “shall not”, and “PROHIBITED” indicate behaviour that is prohibited, i.e. that if performed means the implementation is not in compliance.

Recommended (or should).

– These features add functionality supported by OIC Core Architecture and should be implemented. Recommended features take advantage of the capabilities OIC Core Architecture, usually without imposing major increase of complexity. Notice that for compliance testing, if a recommended feature is implemented, it shall meet the specified requirements to be in compliance with these guidelines. Some recommended features could become requirements in the future. The phrase “should not” indicates behaviour that is permitted but not recommended.

Allowed (or allowed).

– These features are neither required nor recommended by OIC Core Architecture, but if the feature is implemented, it shall meet the specified requirements to be in compliance with these guidelines.

– Conditionally allowed (CA) The definition or behaviour depends on a condition. If the specified condition is met, then the definition or behaviour is allowed, otherwise it is not allowed.

Conditionally required (CR)

– The definition or behaviour depends on a condition. If the specified condition is met, then the definition or behaviour is required. Otherwise the definition or behaviour is allowed as default unless specifically defined as not allowed.

DEPRECATED

– Although these features are still described in this document, they should not be implemented except for backward compatibility. The occurrence of a deprecated feature during operation of an implementation compliant with the current document has no effect on the implementation’s operation and does not produce any error conditions. Backward compatibility may require that a feature is implemented and functions as specified but it shall never be used by implementations compliant with this document.

Strings that are to be taken literally are enclosed in “double quotes”.

Words that are emphasized are printed in italic.
5 OCF Bridge device

5.1 Introduction

This clause describes the functionality of an OCF Bridge Device; such a device is illustrated in Figure 1.

An OCF Bridge Device is a device that represents one or more Bridged Devices as Virtual OCF Devices on the network and/or represents one or more OCF Devices as Virtual Devices using another protocol on the network. The Bridged Devices themselves are out of the scope of this document. The only difference between a native OCF Device and a Virtual Bridged Device is how the device is encapsulated in an OCF Bridge Device.

An OCF Bridge Device shall be indicated on the OCF Security Domain with a Device Type of “oic.d.bridge”. This provides to an OCF Client an explicit indication that the discovered Device is performing a bridging function. This is useful for several reasons; 1) when establishing a home network, the Client can determine that the bridge is reachable and functional when no bridged devices are present, 2) allows for specific actions to be performed on the bridge considering the known functionality a bridge supports, 3) allows for explicit discovery of all devices that are serving a bridging function which benefits trouble shooting and maintenance actions on behalf of a user. When such a device is discovered the exposed Resources on the OCF Bridge Device describe other devices. For example, as shown in Figure 2.

Bridged Devices

- Fan
- Light 1
- Light 2

**Figure 2 – Schematic overview of an OCF Bridge Device bridging non-OCF devices**

It is expected that the OCF Bridge Device creates a set of devices during the start-up of the OCF Bridge Device. The exposed set of Virtual OCF Devices can change as Bridged Devices are added or removed from the bridge. The adding and removing of Bridged Devices is implementation dependent. When an OCF Bridge Device changes the set of exposed Virtual OCF Devices, it shall notify any OCF Clients subscribed to its "/oic/res".

5.2 Symmetric vs. asymmetric bridging

There are two kinds of bridging: Symmetric, Asymmetric. In symmetric bridging, a bridge device exposes OCF server(s) to another ecosystem and exposes other ecosystem’s server(s) to OCF. In asymmetric bridging, a bridge device exposes OCF server(s) to another ecosystem or exposes another ecosystem’s server(s) to OCF, but not both. The former case is called an Asymmetric Server Bridge (see Figure 3), the latter case is called an Asymmetric Client Bridge (see Figure 4).
In Figure 3 each Bridged Server is exposed as a Virtual OCF Server to OCF side. These Virtual OCF Servers are same as normal OCF Servers except that they have additional rt value ("oic.d.virtual") for "/oic/d". The details of the Virtual Bridged Client are not in scope of this document.

Figure 4 shows that each access to the OCF Server is modelled as a Virtual OCF Client. Those accesses can be aggregated if their target OCF servers and access permissions are same, therefore a Virtual OCF Client can tackle multiple Bridged Clients.
5.3 General requirements

The translator shall check the protocol-independent UUID ("piid" in OCF) of each device and shall not advertise back into a Bridged Protocol a device originally seen via that Bridged Protocol. The translator shall stop translating any Bridged Protocol device exposed in OCF via another translator if the translator sees the device via the Bridged Protocol. Similarly, the translator shall not advertise an OCF Device back into OCF, and the translator shall stop translating any OCF device exposed in the Bridged Protocol via another translator if the translator sees the device via OCF. These require that the translator can determine when a device is already being translated. A Virtual OCF Device shall be indicated on the OCF Security Domain with a Device Type of "oic.d.virtual". This allows translators to determine if a device is already being translated when multiple translators are present. How a translator determines if a device is already being translated on a non-OCF Security Domain is described in the protocol-specific clauses (e.g. clause 6).

The translator shall detect duplicate virtual devices (with the same protocol-independent UUID) present in a network and shall not create more than one corresponding virtual device as it translates those duplicate devices into another network.

Each Bridged Server shall be exposed as a separate Virtual OCF Server, with its own OCF Endpoint, and its own "/oic/d" and "/oic/p". The Virtual OCF Server's "/oic/res" resource would be the same as for any ordinary OCF Server that uses a resource directory. That is, it does not respond to multicast discovery requests (because the OCF Bridge Device responds on its behalf), but a unicast query elicits a response listing its own resources with a "rel=hosts" relationship, and an appropriate "anchor" to indicate that it is not the OCF Bridge Device itself. This allows platform-specific, device-specific, and resource-specific fields to all be preserved across translation.

The introspection data provided by the translator shall include information about all the virtual devices (and their resources) exposed by the translator at that point in time. This means that the introspection data provided by the translator before and after a new virtual device is exposed would be different.

5.4 Resource discovery

An OCF Bridge Device shall detect devices that arrive and leave the Bridged network or the OCF Security Domain. Where there is no pre-existing mechanism to reliably detect the arrival and departure of devices on a network, an OCF Bridge Device shall periodically poll the network to detect arrival and departure of devices, for example using COAP multicast discovery (a multicast RETRIEVE of "/oic/res") in the case of the OCF Security Domain. OCF Bridge Device implementations are encouraged to use a poll interval of 30 seconds plus or minus a random delay of a few seconds.

An OCF Bridge Device shall respond to network discovery commands on behalf of the exposed bridged devices. All bridged devices with all their Resources shall be listed in "/oic/res" of the Bridge. The response to a RETRIEVE on "/oic/res" shall only include the devices that match the RETRIEVE request.

The resource reference determined from each Link exposed by "/oic/res" on the Bridge shall be unique. The Bridge shall meet the requirements defined in ISO/IEC 30118-1:2018 for population of the Properties and Link parameters in "/oic/res".

For example, if an OCF Bridge Device exposes Virtual OCF Servers for the fan and lights shown in Figure 2, the bridge might return the example payload in Figure 5 to a Client doing a RETRIEVE on "/oic/res". (Note that what is returned is not in the JSON format but in a suitable encoding as defined in ISO/IEC 30118-1:2018)

Figure 5 illustrates that each Virtual OCF Server has its own "di" and OCF Endpoint exposed by the bridge, and that "/oic/p" and "oic/d" are available for each Virtual OCF Server.

}
When translating a service between a Bridged Protocol (e.g., AllJoyn) and OCF protocols, there are two possible types of translation. Translators are expected to dedicate most of their logic to "deep translation" types of communication, in which data models used with the Bridged Protocol are mapped to the equivalent OCF Resource Types and vice-versa, in such a way that a compliant OCF Client or Bridged Client would be able to interact with the service without realising that a translation was made.

"Deep translation" is out of the scope of this document, as the procedure far exceeds mapping of types. For example, clients on one side of a translator may decide to represent an intensity as an 8-bit value between 0 and 255, whereas the devices on the other may have chosen to represent that as a floating-point number between 0.0 and 1.0. It's also possible that the procedure may require storing state in the translator. Either way, the programming of such translation will require dedicated effort and study of the mechanisms on both sides.

The other type of translation, the "on-the-fly" or "one-to-one" translation, requires no prior knowledge of the device-specific schema in question on the part of the translator. The burden is,

Figure 5 – /oic/res example response

5.5 "Deep translation" vs. "on-the-fly"
instead, on one of the other participants in the communication, usually the client application. That stems from the fact that "on-the-fly" translation always produces Bridged Resource Types and OCF Resource Types as vendor extensions.

For AllJoyn, deep translation is specified in ISO/IEC 30118-6:2018, and on-the-fly translation is covered in clause 7.2 of this document.

5.6 Use of introspection

Whenever possible, the translation code should make use of metadata available that indicates what the sender and recipient of the message in question are expecting. For example, devices that are AllJoyn Certified are required to carry the introspection data for each object and interface they expose. When the metadata is available, translators should convert the incoming payload to exactly the format expected by the recipient and should use information when translating replies to form a more useful message.

For example, for an AllJoyn translator, the expected interaction list is presented in Table 1.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Sender</th>
<th>Receiver</th>
<th>Metadata</th>
</tr>
</thead>
<tbody>

<td>Available</td>
</tr>
<tr>
<td>Response</td>
<td>OCF 1.0</td>
<td>AllJoyn 16.10</td>
<td>Available</td>
</tr>
</tbody>
</table>

5.7 Stability and loss of data

Round-tripping through the translation process specified in this document is not expected to reproduce the same original message. The process is, however, designed not to lose data or precision in messages, though it should be noted that both OCF and AllJoyn payload formats allow for future extensions not considered in this document.

However, a third round of translation should produce the same identical message as was previously produced, provided the same information is available. That is, in the chain shown in Figure 6, payloads 2 and 4 as well as 3 and 5 should be identical.

Figure 6 – Payload Chain.

5.8 Security

5.8.1 General Security Requirements

The OCF Bridge Device shall go through OCF ownership transfer as any other onboardee would. Separately, it shall go through the Bridged Protocol's ownership transfer mechanism (e.g., AllJoyn claiming) normally as any other onboardee would.

The OCF Bridge Device shall be field updatable.

Unless an administrator opts in to allow it (see 8.2), a translator shall not expose connectivity to devices to which it cannot get a secure connection.
Each Virtual OCF Device shall be provisioned for security by an OCF Onboarding tool. Each Virtual Bridged Device should be provisioned as appropriate in the Bridged ecosystem. In other words, Virtual Devices are treated the same way as physical Devices. They are entities that have to be provisioned in their network.

The Translator shall provide a "piid" value that can be used to correlate a non-OCF Device with its corresponding Virtual OCF Device, as specified in 5.3. An Onboarding Tool might use this correlation to improve the Onboarding user experience by eliminating or reducing the need for user input, by automatically creating security settings for Virtual OCF Devices that are equivalent to the security settings of their corresponding non-OCF Devices. See ISO/IEC 30118-2:2018 for detailed information about Onboarding.

Each Virtual Device shall implement the security requirements of the ecosystem that it is connected to. For example, each Virtual OCF Device shall implement the behaviour required by ISO/IEC 30118-1:2018 and ISO/IEC 30118-2:2018. Each Virtual OCF Device shall perform authentication, access control, and encryption according to the security settings it received from the Onboarding Tool.

Depending on the architecture of the Translator, authentication and access control might take place just within each ecosystem, but not within the Translator. For example, when an OCF Client sends a request to a Virtual OCF Server:

- Authentication and access control might be performed by the Virtual OCF Server when receiving the request from the OCF Client.
- The Translator might not perform authentication or access control when the request travels through the Translator to the corresponding Virtual Bridged Client.
- Authentication and access control might be performed by the target Bridged Server when it receives the request from the Virtual Bridged Client, according to the security model of the Bridged ecosystem.

A Translator may receive unencrypted data coming from a Bridged Client through a Virtual Bridged Device. The translated message shall be encrypted by the corresponding Virtual OCF Client, before sending it to the target OCF Device, if this OCF Device requires encryption.

A Translator may receive unencrypted data coming from an OCF Client through a Virtual OCF Server. After translation, this data shall be encrypted by the corresponding Virtual Bridged Client, before sending it to the target Bridged Server, if this Bridged Server requires encryption.

A Translator shall protect the data while that data travels between a Virtual Client and a Virtual Server, through the Translator. For example, if the Translator sends data over a network, the Translator shall perform appropriate authentication and access control, and shall encrypt the data, between all peers involved in this communication.

### 5.8.2 Blocking communication of Bridged Devices with the OCF ecosystem

An OCF Onboarding Tool shall be able to block the communication of all OCF Devices with all Bridged Devices that don’t communicate securely with the Bridge, by using the Bridge Device’s "oic.r.securemode" Resource.

In addition, an OCF Onboarding Tool can block the communication of a particular Virtual OCF Client with all OCF Servers, or block the communication of all OCF Clients with a particular Virtual OCF Server, in the same way as it would for any other OCF Device. See ISO/IEC 30118-2:2018 for information about the soft reset state.
6 AllJoyn translation

6.1 Operational scenarios

The overall goals are to:

1) make Bridged Servers appear to OCF clients as if they were native OCF servers, and
2) make OCF servers appear to Bridged Clients as if they were native non-OCF servers.

6.2 Requirements specific to an AllJoyn translator

6.2.1 Introduction

The translator shall be an AllJoyn Router Node. (This is a requirement so that users can expect that a certified OCF Bridge Device will be able to talk to any AllJoyn device, without the user having to buy some other device.)

The requirements in clause 6.2 apply when using algorithmic translation, and by default apply to deep translation unless the relevant clause for such deep translation specifies otherwise.

6.2.2 Exposing AllJoyn producer devices to OCF clients

6.2.2.1 Virtual OCF Devices and Resources

As specified in ISO/IEC 30118-2:2018 the value of the “di” property of OCF Devices (including Virtual OCF Devices) shall be established as part of Onboarding of that Virtual OCF Device.

Each AllJoyn object shall be mapped to one or more Virtual OCF Resources. If all AllJoyn interfaces can be translated to resource types on the same resource, there should be a single Virtual OCF Resource, and the path component of the URI of the Virtual OCF Resource shall be the AllJoyn object path, where each “_h” in the AllJoyn object path is transformed to “-” (hyphen), each “_d” in the AllJoyn object path is transformed to “.” (dot), each “_t” in the AllJoyn object path is transformed to “~” (tilde), and each “_u” in the AllJoyn object path is transformed to “_” (underscore). Otherwise, a Resource with that path shall exist with a Resource Type of [“oic.wk.col”, “oic.r.alljoynobject”] which is a Collection of links, where “oic.r.alljoynobject” is defined in clause 8.2 and the items in the collection are the Resources with the translated Resource Types.

The value of the “piid” property of “/oic/d” for each Virtual OCF Device shall be the value of the OCF-defined AllJoyn field “org.openconnectivity.piid” in the AllJoyn About Announce signal, if that field exists, else it shall be calculated by the Translator as follows:

- If the AllJoyn device supports security, the value of the “piid” property value shall be the peer GUID.
- If the AllJoyn device does not support security but the device is being bridged anyway (see 8.2), the “piid” property value shall be derived from the Deviceld and Appld properties (in the About data), by concatenating the Deviceld value (not including any null termination) and the Appld bytes and using the result as the “name” to be used in the algorithm specified in IETF RFC 4122 clause 4.3, with SHA-1 as the hash algorithm, and 8f0e4e90-79e5-11e6-bdf4-0800200c9a66 as the name space ID. (This is to address the problem of being able to de-duplicate AllJoyn devices exposed via separate OCF Bridge Devices.)

A translator implementation is encouraged to listen for AllJoyn About Announce signals matching any AllJoyn interface name. It can maintain a cache of information it received from these signals, and use the cache to quickly handle “/oic/res” queries from OCF Clients (without having to wait for Announce signals while handling the queries).
A translator implementation is encouraged to listen for other signals (including EmitsChangedSignal of properties) only when there is a client subscribed to a corresponding resource on a Virtual AllJoyn Device.

There are multiple types of AllJoyn interfaces, which shall be handled as follows.

1) If the AllJoyn interface is in a well-defined set (defined in ISO/IEC 30118-6:2018 or 6.2.2.2) of interfaces where standard forms exist on both the AllJoyn and OCF sides, the translator shall either:
   a) follow the specification for translating that interface specially, or
   b) not translate the AllJoyn interface.

2) If the AllJoyn interface is not in the well-defined set, the translator shall either:
   a) not translate the AllJoyn interface, or
   b) algorithmically map the AllJoyn interface as specified in 6.3 to custom/vendor-defined Resource Types by converting the AllJoyn interface name to OCF resource type name(s).

An AllJoyn interface name shall be converted to a Device Type or a set of one or more OCF Resource Types as follows:

1) If the AllJoyn interface has any members, append a suffix ".<seeBelow>" where <seeBelow> is described in this clause.

2) For each upper-case letter present in the entire string, replace it with a hyphen followed by the lower-case version of that letter (e.g., convert "A" to "-a").

3) If an underscore appears followed by a (lower-case) letter or a hyphen, for each such occurrence, replace the underscore with two hyphens (e.g., convert "_a" to "--a", "_-a" to "---a").

4) For each underscore remaining, replace it with a hyphen (e.g., convert "_1" to "-1").

5) Prepend the "x." prefix.

Some examples are shown in Table 2. The first three are normal AllJoyn names converted to unusual OCF names. The last three are unusual AllJoyn names converted (perhaps back) to normal OCF names. ("xn--" is a normal domain name prefix for the Punycode-encoded form of an Internationalized Domain Name, and hence can appear in a normal vendor-specific OCF name.)

</tbody>
</table>

Table 2 – AllJoyn to OCF Name Examples

Each AllJoyn interface that has members and is using algorithmic mapping shall be mapped to one or more Resource Types as follows:

- AllJoyn Properties with the same EmitsChangedSignal value are mapped to the same Resource Type where the value of the <seeBelow> label is the value of EmitsChangedSignal. AllJoyn Properties with EmitsChangedSignal values of "const" or "false", are mapped to Resources that are not Observable, whereas AllJoyn Properties with EmitsChangedSignal values of "true" or...
"invalidates" result in Resources that are Observable. The Version property in an AllJoyn interface is always considered to have an EmitsChangedSignal value of "const", even if not specified in introspection XML. The name of each property on the Resource Type shall be "<ResourceType>.<AllJoynPropertyName>", where each "_d" in the <AllJoynPropertyName> is transformed to "." (dot), and each "_h" in the <AllJoynPropertyName> is transformed to "-" (hyphen).

- Resource Types mapping AllJoyn Properties with access "readwrite" shall support the "oic.if.rw" OCF Interface. Resource Types mapping AllJoyn Properties with access "read" shall support the "oic.if.r" OCF Interface. Resource Types supporting both the "oic.if.rw" and "oic.if.r" OCF Interfaces shall choose "oic.if.r" as the default Interface.

- Each AllJoyn Method is mapped to a separate Resource Type, where the value of the <seeBelow> label is the AllJoyn Method name. The Resource Type shall support the "oic.if.rw" OCF Interface. Each argument of the AllJoyn Method shall be mapped to a separate Property on the Resource Type, where the name of that Property is prefixed with "<ResourceType>arg<#>", where <#> is the 0-indexed position of the argument in the AllJoyn introspection xml, in order to help get uniqueness across all Resource Types on the same Resource. Therefore, when the AllJoyn argument name is not specified, the name of that property is "<ResourceType>arg<#>", where <#> is the 0-indexed position of the argument in the AllJoyn introspection XML. In addition, that Resource Type has an extra "<ResourceType>validity" property that indicates whether the rest of the properties have valid values. When the values are sent as part of an UPDATE response, the validity property is true, and any other properties have valid values. In a RETRIEVE (GET or equivalent in the relevant transport binding) response, the validity property is false, and any other properties can have meaningless values. If the validity property appears in an UPDATE request, its value shall be true (a value of false shall result in an error response).

- Each AllJoyn Signal (whether sessionless, sessioncast, or unicast) is mapped to a separate Resource Type on an Observable Resource, where the value of the <seeBelow> label is the AllJoyn Signal name. The Resource Type shall support the "oic.if.r" OCF Interface. Each argument of the AllJoyn Signal is mapped to a separate Property on the Resource Type, where the name of that Property is prefixed with "<ResourceType>arg<#>", where <#> is the 0-indexed position of the argument in the AllJoyn introspection xml, in order to help get uniqueness across all Resource Types on the same Resource. Therefore, when the AllJoyn argument name is not specified, the name of that property is "<ResourceType>arg<#>", where <#> is the 0-indexed position of the argument in the AllJoyn introspection XML. In addition, that Resource Type has an extra "<ResourceType>validity" property that indicates whether the rest of the properties have valid values. When the values are sent as part of a NOTIFY response, the validity property is true, and any other properties have valid values. In a RETRIEVE (GET or equivalent in the relevant transport binding) response, the validity property is false, and any other properties returned can have meaningless values. This is because in AllJoyn, the signals are instantaneous events, and the values are not necessarily meaningful beyond the lifetime of that message. Note that AllJoyn does have a TTL field that allows store-and-forward signals, but such support is not required in OCF 1.0. We expect that in the future, the TTL may be used to allow valid values in response to a RETRIEVE that is within the TTL.

When an algorithmic mapping is used, AllJoyn data types shall be mapped to OCF property types according to 6.3.

If an AllJoyn operation fails, the translator shall send an appropriate OCF error response to the OCF client. If an AllJoyn error name is available and does not contain the "org.openconnectivity.Error.Code" prefix, it shall construct an appropriate OCF error message (e.g., diagnostic payload if using CoAP) from the AllJoyn error name and AllJoyn error message (if any), using the form "<error name>: <error message>", with the <error name> taken from the AllJoyn error name field and the <error message> taken from the AllJoyn error message, and the CoAP error code set to an appropriate value (if CoAP is used). If an AllJoyn error name is available and
contains the "org.openconnectivity.Error.Code" prefix, the OCF error message (e.g., diagnostic
payload if using CoAP) should be taken from the AllJoyn error message (if any), and the CoAP
error code (if CoAP is used) set to a value derived as follows; remove the
"org.openconnectivity.Error.Code" prefix, and if the resulting error name is of the form "<#>" where
<#> is an error code without a decimal (e.g., "404"), the CoAP error code shall be the error code
indicated by the "<#>". Example: "org.openconnectivity.Error.Code404" becomes "404", which
shall result in an error 4.04 for a CoAP transport.

6.2.2.2 Exposing an AllJoyn producer application as a Virtual OCF Server

Table 3 shows how OCF Device properties, as specified in Table 27 in ISO/IEC 30118-1:2018 shall
be derived, typically from fields specified in the AllJoyn About Interface Specification and AllJoyn
Configuration Interface Specification.

If the AllJoyn About or Config data field has a mapping rule defined (as in Table 3, Table 4, Table 5,
and Table 6), the field name shall be translated based on that mapping rule; else if the AllJoyn
About or Config data field has a fully qualified name (with a <domain> prefix (such as
"com.example", "org.alljoyn"), the field name shall be translated based on the rules specified in
6.2.2 for mapping AllJoyn fields; else, the field shall not be translated as it may be incorrect (error)
or it has no valid mapping (such as daemonRealm and passCode).

The syntax is a comma separated list of "<vertical>.major.min or". <vertical> is the name of the vertical (i.e. sh for Smart Home) | Y | Comma separated list of the Version property values of each interface listed in the objectDescription argument of the Announce signal of About. In addition to the mandatory values specified in ISO/IEC 30118-1:2018, additional values are formatted as "x.<interface name> <Version property value>". This document assumes that the value of the Version property is the same as the value of the "org.gtk.GDBus.Service" annotation of the interface in the AllJoyn introspection XML, and therefore the value of the Version property may be determined through introspection alone. Note that AllJoyn specifies that the default value is 1 if the "org.gtk.GDBus.Service" annotation is absent. | N, but required by IRB for all standard interfaces, and absence can be used to imply a constant (e.g., 0) |
| Localized Descriptions | ld | Detailed description of the Device, in one or more languages. This property is an array of objects where each object has a 'language' field (containing an RFC 5646 language tag) and a 'value' field containing the device description in the indicated language. | N | Description | Y |
| Software Version | sv | Version of the device software. | N | SoftwareVersion | Y |
| Manufacturer Name | dmn | Name of manufacturer of the Device, in one or more languages. This property is an array of objects. | N | Manufacturer | Y |
where each object has a ‘language’ field (containing an RFC 5646 language tag) and a ‘value’ field containing the manufacturer name in the indicated language.

| Model Number | dmno | Model number as designated by manufacturer. | N | ModelNumber | The app model number. | Y |

In addition, any additional vendor-defined fields in the AllJoyn About data shall be mapped to vendor-defined properties in the OCF Device resource “/oic/d” (which implements the “oic.wk.d” resource type), with a property name formed by prepending “x.” to the AllJoyn field name.

Table 4 shows how OCF Device Configuration properties, as specified in Table 22 in ISO/IEC 30118-1:2018 shall be derived:

**Table 4 – oic.wk.con resource type definition**

</tr>
</tbody>
</table>

In addition, the “oic.wk.mnt” properties Factory_Reset (“fr”) and Reboot (“rb”) shall be mapped to AllJoyn Configuration methods FactoryReset and Restart, respectively.

6.2.3 Exposing OCF resources to AllJoyn consumer applications

6.2.3.1 Use of AllJoyn Producer Application

Unless specified otherwise, each OCF resource shall be mapped to a separate AllJoyn object.

Each OCF Server shall be exposed as a separate AllJoyn producer application, with its own About data. This allows platform-specific, device-specific, and resource-specific fields to all be preserved across translation. However, this requires that AllJoyn Claiming of such producer applications be solved in a way that does not require user interaction, but this is left as an implementation issue.

The AllJoyn producer application shall implement the “oic.d.virtual” AllJoyn interface. This allows translators to determine if a device is already being translated when multiple translators are present. The “oic.d.virtual” interface is defined as follows:

```xml
<interface name="oic.d.virtual"/>
```

The implementation may choose to implement this interface by the AllJoyn object at path “/oic/d”.

The AllJoyn peer ID shall be the OCF device ID (“di”).

Unless specified otherwise, the AllJoyn object path shall be the OCF URI path, where each “-” (hyphen) in the OCF URI path is transformed to “_h”, each “.” (dot) in the OCF URI path is transformed to “_d”, each “~” (tilde) in the OCF URI path is transformed to “_t”, and each “_” (underscore) in the OCF URI path is transformed to “_u”.

The AllJoyn About data shall be populated per Table 8.

A translator implementation is encouraged to maintain a cache of OCF resources to handle the implementation of queries from the AllJoyn side, and emit an Announce Signal for each OCF Server. Specifically, the translator could always Observe “/oic/res” changes and only Observe other resources when there is a client with a session on a Virtual AllJoyn Device.

There are multiple types of resources, which shall be handled as follows.
1) If the Resource Type is in a well-defined set (defined in ISO/IEC 30118-6:2018 or 6.2.3.2) of resource types where standard forms exist on both the AllJoyn and OCF sides, the translator shall either:
   a) follow the specification for translating that resource type specially, or
   b) not translate the Resource Type.

2) If the Resource Type is not in the well-defined set (but is not a Device Type), the translator shall either:
   a) not translate the Resource Type, or
   b) algorithmically map the Resource Type as specified in 6.3 to a custom/vendor-defined AllJoyn interface by converting the OCF Resource Type name to an AllJoyn Interface name.

An OCF Resource Type or Device Type shall be converted to an AllJoyn interface name as follows:

1) Remove the “x.” prefix if present
2) For each occurrence of a hyphen (in order from left to right in the string):
   a) If the hyphen is followed by a letter, replace both characters with a single upper-case version of that letter (e.g., convert “-a” to “A”).
   b) Else, if the hyphen is followed by another hyphen followed by either a letter or a hyphen, replace two hyphens with a single underscore (e.g., convert “--a” to “_a”, “---” to “_”).
   c) Else, convert the hyphen to an underscore (i.e., convert “-” to “_”).

Some examples are shown in the Table 7. The first three are unusual OCF names converted (perhaps back) to normal AllJoyn names. The last three are normal OCF names converted to unusual AllJoyn names. (“xn--” is a normal domain name prefix for the Punycode-encoded form of an Internationalized Domain Name, and hence can appear in a normal vendor-specific OCF name.)

<table>
<thead>
<tr>
<th>From OCF name</th>
<th>To AllJoyn name</th>
</tr>
</thead>
<tbody>
<tr>
<td>x.example.-widget</td>
<td>example.Widget</td>
</tr>
<tr>
<td>x.example.my-----widget</td>
<td>example.my__widget</td>
</tr>
<tr>
<td>x.example.-my---widget</td>
<td>example.My_Widget</td>
</tr>
<tr>
<td>x.xn--p1ai.example</td>
<td>xn_p1ai.example</td>
</tr>
<tr>
<td>x.xn--90ae.example</td>
<td>xn__90ae.example</td>
</tr>
<tr>
<td>x.example.my-name_1</td>
<td>example.myName_1</td>
</tr>
</tbody>
</table>

An OCF Device Type is mapped to an AllJoyn interface with no members.

Unless specified otherwise, each OCF Resource Type shall be mapped to an AllJoyn interface as follows:

- Each OCF property is mapped to an AllJoyn property in that interface, where each “.” (dot) in the OCF property is transformed to “_d”, and each “-” (hyphen) in the OCF property is transformed to “_h”.
- The EmitsChangedSignal value for each AllJoyn property shall be set to “true” if the resource supports NOTIFY, or “false” if it does not. (The value is never set to “const” or “invalidates” since those concepts cannot currently be expressed in OCF.)
- The “access” attribute for each AllJoyn property shall be “read” if the OCF property is read-only, or “readwrite” if the OCF property is read-write.
--- If the resource supports DELETE, a Delete() method shall appear in the interface.

--- If the resource supports CREATE, a Create() method shall appear in the interface, with input arguments of each property of the resource to create. (Such information is not available algorithmically can be determined via introspection.) If such information is not available, a CreateWithDefaultValues() method shall appear which takes no input arguments. In either case, the output argument shall be an OBJECT_PATH containing the path of the created resource.

--- If the resource supports UPDATE (i.e., the “oic.if.rw" or “oic.if.a" OCF Interface) then an AllJoyn property set operation (i.e., an org.freedesktop.DBus.Properties.Set() method call) shall be mapped to a Partial UPDATE (e.g., POST in CoAP) with the corresponding OCF property.

--- If a Resource has a Resource Type “oic.r.alljoynobject”, then instead of separately translating each of the Resources in the collection to its own AllJoyn object, all Resources in the collection shall instead be translated to a single AllJoyn object whose object path is the OCF URI path of the collection.

OCF property types shall be mapped to AllJoyn data types according to 6.3.

If an OCF operation fails, the translator shall send an appropriate AllJoyn error response to the AllJoyn consumer. If an error message is present in the OCF response, and the error message (e.g., diagnostic payload if using CoAP) fits the pattern “<error name>: <error message>” where <error name> conforms to the AllJoyn error name syntax requirements, the AllJoyn error name and AllJoyn error message shall be extracted from the error message in the OCF response. Otherwise, the AllJoyn error name shall be "org.openconnectivity.Error.Code<#>" where <#> is the error code (e.g., CoAP error code) in the OCF response without a decimal (e.g., "404") and the AllJoyn error message is the error message in the OCF response.

### 6.2.3.2 Exposing an OCF server as a Virtual AllJoyn Producer

The object description returned in the About interface shall be formed as specified in the AllJoyn About Interface Specification, and Table 8 shows how AllJoyn About Interface fields shall be derived, based on properties in “oic.wk.d”, “oic.wk.con”, “oic.wk.p”, and “oic.wk.con.p”.

The AllJoyn field “org.openconnectivity.loc” shall be neither announced nor localized and its D-Bus type signature shall be “ad”. All other AllJoyn field names listed in Table 5 which have the prefix “org.openconnectivity.” shall be neither announced nor localized and their D-Bus type signature shall be “s”.

In addition, the Configuration methods FactoryReset and Restart shall be mapped to “oic.wk.mnt” properties Factory_Reset (“fr”) and Reboot (“rb”), respectively, and any additional vendor-defined properties in the OCF Configuration resource (which implements the “oic.wk.con” resource type and optionally the “oic.wk.con.p” resource type) shall be mapped to vendor-defined fields the AllJoyn Configuration data, with a field name formed by removing the leading “x.” from the property name.

6.3 On-the-Fly Translation from D-Bus and OCF payloads

6.3.1 Introduction

The “dbus1” payload format is specified in the D-Bus Specification and AllJoyn adopted the D-Bus protocol and made it distributed over the network. The modifications done by AllJoyn to the format
are all in the header part of the packet, not in the data payload itself, which remains compatible with "dbus1". Other variants of the protocol that have been proposed by the Linux community ("GVariant" and "kdbus" payloads) contain slight incompatibilities and are not relevant for this discussion.

6.3.2 Translation without aid of introspection

6.3.2.1 Introduction

Clause 6.3.2 describes how translators shall translate messages between the two payload formats in the absence of introspection metadata from the actual device. This situation arises in the when there is content not described by introspection, such as the inner payload of AllJoyn properties of type “D-Bus VARIANT”.

Since introspection is not available, the translator cannot know the rich JSON sub-type, only the underlying CBOR type and from that it can infer the JSON generic type, and hence translation is specified in terms of those generic types.

6.3.2.2 Booleans

Boolean conversion is trivial since both sides support this type.

<table>
<thead>
<tr>
<th>D-Bus type</th>
<th>JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;b&quot; – BOOLEAN</td>
<td>boolean (true or false)</td>
</tr>
</tbody>
</table>

6.3.2.3 Numeric types

The translation of numeric types is lossy and that is unavoidable due to the limited expressiveness of the JSON generic types. This can only be solved with introspection.

The translation of numeric types is direction-specific.

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>

</tr>
<tr>
<td>&quot;x&quot; - INT64 (signed 64-bit)</td>
<td></td>
</tr>
<tr>
<td>&quot;d&quot; - DOUBLE (IEEE 754 double precision)</td>
<td></td>
</tr>
</tbody>
</table>

a D-Bus payloads of types "t" (UINT64) and "x" (INT64) can contain values that cannot be perfectly represented in IEEE 754 double-precision floating point. The RFCs governing JSON do not forbid such numbers but caution that many implementations may not be able to deal with them. Currently, OCF transports its payload using CBOR instead of JSON, which can represent those numbers with fidelity. However, it should be noted that ISO/IEC 30118-1:2018 does not allow for integral numbers outside the range \(-2^{53} < x < 2^{53}\).
Table 12 – Numeric type translation, JSON to D-Bus

<table>
<thead>
<tr>
<th>From JSON type</th>
<th>To D-Bus type</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>“d” - DOUBLEa</td>
</tr>
</tbody>
</table>

a To provide the most predictable result, all translations from OCF to AllJoyn produce values of type “d” DOUBLE (IEEE 754 double precision).

6.3.2.4 Text strings

Table 13 – Text string translation

<table>
<thead>
<tr>
<th>D-Bus type</th>
<th>JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“s” – STRING</td>
<td>string</td>
</tr>
</tbody>
</table>

Conversion between D-Bus and JSON strings is simple, as both require their content to be valid Unicode. For example, an implementation can typically do a direct byte copy, as both protocols specify UTF-8 as the encoding of the data, neither constrains the data to a given normalisation format nor specify whether private-use characters or non-characters should be disallowed.

Since the length of D-Bus strings is always known, it is recommended translators not use CBOR indeterminate text strings (first byte 0x7f).

6.3.2.5 Byte arrays

The translation of a byte array is direction-specific.

Table 14 – Byte array translation

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“ay” - ARRAY of BYTE</td>
<td>(base64-encoded) string</td>
</tr>
</tbody>
</table>

The base64url encoding is specified in IETF RF 4648 clause 5.

6.3.2.6 D-Bus variants

Table 15 – D-Bus variant translation

<table>
<thead>
<tr>
<th>D-Bus type</th>
<th>JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“v” – VARIANT</td>
<td>see clause 6.3.2.6</td>
</tr>
</tbody>
</table>

D-Bus has a type called VARIANT (“v”) that is a wrapper around any other D-Bus type. It’s a way for the type system to perform type-erasure. JSON, on the other hand, is not type-safe, which means that all JSON values are, technically, variants. The conversion for a D-Bus variant to JSON is performed by entering that variant and encoding the type carried inside as per the rules in this document.

The algorithm must be recursive, as D-Bus variants are allowed to contain variants themselves.
6.3.2.7  D-Bus object paths and signatures

The translation of D-Bus object paths and signatures is unidirectional (there is no mapping to them, only from them). This is shown in Table 16. In the reverse direction, clause 6.3.2.4 always converts to D-Bus STRING rather than OBJECT_PATH or SIGNATURE since it is assumed that “s” is the most common string type in use.

Table 16 – D-Bus object path translation

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“o” – OBJECT_PATH</td>
<td>string</td>
</tr>
<tr>
<td>“g” – SIGNATURE</td>
<td></td>
</tr>
</tbody>
</table>

Both D-Bus object paths and D-Bus type signatures are US-ASCII strings with specific formation rules, found in the D-Bus Specification. They are very seldom used and are not expected to be found in resources subject to translation without the aid of introspection.

6.3.2.8  D-Bus structures

The translation of the types in Table 17 is direction-specific:

Table 17 – D-Bus structure translation

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“r” – STRUCT</td>
<td>array, length &gt; 0</td>
</tr>
</tbody>
</table>

D-Bus structures can be interpreted as a fixed-length array containing a pre-determined list of types for each member. This is how such a structure is mapped to JSON: as an array of heterogeneous content, which are the exact members of the D-Bus structure, in the order in which they appear in the structure.

6.3.2.9  Arrays

The translation of the types in Table 18 is bidirectional:

Table 18 – Byte array translation

<table>
<thead>
<tr>
<th>D-Bus type</th>
<th>JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“ay” - ARRAY of BYTE</td>
<td>(base64-encoded) string – see 6.3.2.5</td>
</tr>
<tr>
<td>“ae” - ARRAY of DICT_ENTRY</td>
<td>object – see 6.3.2.10</td>
</tr>
</tbody>
</table>

The translation of the types in Table 19 is direction-specific:

Table 19 – Other array translation

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>“a” – ARRAY of anything else not specified</td>
<td>array</td>
</tr>
</tbody>
</table>
Aside from arrays of bytes and arrays of dictionary entries, which are mapped to JSON strings and objects respectively, arrays in JSON cannot be constrained to a single type (i.e., heterogeneous arrays). For that reason, strictly speaking all D-Bus arrays excepting arrays of bytes and arrays of dictionary entries must first be converted to arrays of variant “av” and then that array can be converted to JSON. See Table 20.

### Table 20 – JSON array translation

<table>
<thead>
<tr>
<th>From JSON type</th>
<th>Condition</th>
<th>To D-Bus type</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>length=0</td>
<td>“av” – ARRAY of VARIANT</td>
</tr>
<tr>
<td>array</td>
<td>length&gt;0, all elements of same type</td>
<td>“a” – ARRAY</td>
</tr>
<tr>
<td>array</td>
<td>length&gt;0, elements of different types</td>
<td>“r” – STRUCT</td>
</tr>
</tbody>
</table>

Conversion of D-Bus arrays of variants uses the conversion of variants as specified, which simply eliminates the distinction between a variant containing a given value and that value outside a variant. In other words, the elements of a D-Bus array are extracted and sent as elements of the JSON array, as per the other rules of this document.

#### 6.3.2.10 Dictionaries / Objects

The choice of “dictionary of STRING to VARIANT” is made because that is the most common type of dictionary found in payloads and is an almost perfect superset of all possible dictionaries in D-Bus anyway. Moreover, it can represent JSON Objects with fidelity, which is the representation that OCF uses in its data models, which in turn means those D-Bus dictionaries will be able to carry with fidelity any OCF JSON Object in current use. See Table 21

### Table 21 – D-Bus dictionary translation

<table>
<thead>
<tr>
<th>D-Bus type</th>
<th>JSON type</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;a(sv)&quot; - dictionary of STRING to VARIANT</td>
<td>object</td>
</tr>
</tbody>
</table>

D-Bus dictionaries that are not mapping string to variant are first converted to those constraints and then encoded in CBOR.

#### 6.3.2.11 Non-translatable types

The types in are not translatable, and the translator should drop the incoming message. None of the types in Table 22 are in current use by either AllJoyn or OCF 1.0 devices, so the inability to translate them should not be a problem.

### Table 22 – Non-translation types

<table>
<thead>
<tr>
<th>Type Scope</th>
<th>Type Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D-Bus</td>
<td>&quot;h&quot;</td>

<td></td>
</tr>
<tr>
<td>)}</td>
<td>}</td>
</tr>
</tbody>
</table>

NOTE This value cannot be represented with IEEE754 double-precision floating point without loss of information. It is also outside the currently-allowed range of integrals in OCF.

6.3.3 Translation with aid of introspection

6.3.3.1 Introduction to Introspection Metadata

When introspection is available, the translator can use the extra metadata provided by the side offering the service to expose a higher-quality reply to the other side. This chapter details modifications to the translation described in the previous chapter when the metadata is found.
Introspection metadata can be used for both translating requests to services and replies from those services. When used to translate requests, the introspection is “constraining”, since the translator must conform exactly to what that service expects. When used to translate replies, the introspection is “relaxing”, but may be used to inform the receiver what other possible values may be encountered in the future.

Note that OCF introspection uses JSON types, media attributes, and format attributes, not CBOR encoding. The actual encoding of each JSON type is discussed in clause 12.4 of ISO/IEC 30118-1:2018, JSON format attribute values are as defined in JSON Schema Validation, and JSON media attribute values are as defined in JSON Hyper-Schema.

6.3.3.2 Translation of the introspection itself

Note that both OCF 1.0 and AllJoyn require all services exposed to include introspection metadata, which means the translator will need to translate the introspection information on-the-fly for each OCF resource or AllJoyn producer it finds. The translator shall preserve as much of the original information as can be represented in the translated format. This includes both the information used in machine interactions and the information used in user interactions, such as description and documentation text.

6.3.3.3 Variability of introspection data

Introspection data is not a constant and the translator may find, upon discovering further services, that the D-Bus interface or OCF Resource Type it had previously encountered is different than previously seen. The translator needs to take care about how the destination side will react to a change in introspection.

D-Bus interfaces used by AllJoyn services may be updated to newer versions, which means a given type of service may be offered by two distinct versions of the same interface. Updates to standardised interfaces must follow strict guidelines established by the AllSeen Interface Review Board, mapping each version to a different OCF Resource Type should be possible without much difficulty. However, there’s no guarantee that vendor-specific extensions follow those requirements. Indeed, there’s nothing preventing two revisions of a product to contain completely incompatible interfaces that have the same name and version number.

On the opposite direction, the rules are much laxer. Since OCF specifies optional properties to its Resource Types, a simple monotonically-increasing version number like AllJoyn consumer applications expect is not possible. However, it should be noted that services created by the translator by “on-the-fly” translation will only be accessed by generic client applications. Dedicated applications will only use “deep binding” translation.

6.3.3.4 Numeric types

For numeric values, all D-Bus and JSON numeric types are treated equally as source and may all be translated into any of the other side’s types. When translating a request to a service, the translator need only verify whether there would be loss of information when translating from source to destination. For example, when translating the number 1.5 to either a JSON integer or to one of the D-Bus integral types, there would be loss of information, in which case the translator should refuse the incoming message. Similarly, the value 1,234,567 does not fit the range of a D-Bus byte, 16-bit signed or unsigned integer.

When translating the reply from the service, the translator shall use the following rules.

Table 25 indicates how to translate from a JSON type to the corresponding D-Bus type, where the first matching row shall be used. If the JSON schema does not indicate the minimum value of a JSON integer, 0 is the default. If the JSON schema does not indicate the maximum value of a
JSON integer, $2^{32} - 1$ is the default. The resulting AllJoyn introspection XML shall contain "org.alljoyn.Bus.Type.Min" and "org.alljoyn.Bus.Type.Max" annotations whenever the minimum or maximum, respectively, of the JSON value is different from the natural minimum or maximum of the D-Bus type.

Table 25 – JSON type to D-Bus type translation

<table>
<thead>
<tr>
<th>From JSON type</th>
<th>Condition</th>
<th>To D-Bus Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>minimum $\geq 0$ AND maximum $&lt; 2^8$</td>
<td>&quot;y&quot; (BYTE)</td>
</tr>

<td></td>
<td>minimum $\geq 0$ AND maximum $&lt; 2^{16}$</td>
<td>&quot;q&quot; (UINT16)</td>
</tr>
<tr>
<td></td>
<td>minimum $\geq -2^{15}$ AND maximum $&lt; 2^{15}$</td>
<td>&quot;n&quot; (INT16)</td>
</tr>
<tr>
<td></td>
<td>minimum $\geq 0$ AND maximum $&lt; 2^{32}$</td>
<td>&quot;u&quot; (UINT32)</td>
</tr>
<tr>
<td></td>
<td>minimum $\geq -2^{31}$ AND maximum $&lt; 2^{31}$</td>
<td>&quot;i&quot; (INT32)</td>
</tr>
<tr>
<td></td>
<td>minimum $\geq 0$</td>
<td>&quot;t&quot; (UINT64)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;x&quot; (INT64)</td>
</tr>
</tbody>
</table>

| Number          | "d" (DOUBLE)                           |               |

| String          | pattern = "^0|([-9][0-9]{0,19})$       | "t" (UINT64)  |
|                | pattern = "^0|([-9][0-9]{0,18})$       | "x" (INT64)   |

Table 26 indicates how to translate from a D-Bus type to the corresponding JSON type.

Table 26 – D-Bus type to JSON type translation

<table>
<thead>
<tr>
<th>From D-Bus type</th>
<th>To JSON type</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;y&quot; (BYTE)</td>
<td>integer</td>
<td>&quot;minimum&quot; and &quot;maximum&quot; in the JSON schema shall be set to the value of the &quot;org.alljoyn.Bus.Type.Min&quot; and &quot;org.alljoyn.Bus.Type.Max&quot; (respectively) annotations if present, or to the min and max values of the D-Bus type's range if such annotations are absent.</td>
</tr>
<tr>
<td>&quot;n&quot; (UINT16)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;q&quot; (INT16)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;u&quot; (UINT32)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;i&quot; (INT32)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;t&quot; (UINT64)</td>
<td>integer</td>
<td>IETF RFC 7159 clause 6 explains that higher JSON integers are not interoperable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;x&quot; (INT64)</td>
<td>integer</td>
<td>IETF RFC 7159 clause 6 explains that other JSON integers are not interoperable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>&quot;d&quot; (double)</td>
<td>number</td>
<td></td>
</tr>
</tbody>
</table>
6.3.3.5 Text string and byte arrays

There’s no difference in the translation of text strings and byte arrays compared to clause 6.3.2. Clause 6.3.3 simply lists the JSON equivalent types for the generated OCF introspection. See Table 27.

<table>
<thead>
<tr>
<th>D-Bus Type</th>
<th>JSON Type</th>
<th>JSON media attribute, binaryEncoding property</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;s&quot; – STRING</td>
<td>string</td>
<td>(none)</td>
</tr>
<tr>
<td>&quot;ay&quot; - ARRAY of BYTE</td>
<td>string</td>
<td>base64</td>
</tr>
</tbody>
</table>

In addition, the mapping of the JSON Types in Table 28 is direction-specific:

<table>
<thead>
<tr>
<th>From JSON type</th>
<th>Condition</th>
<th>To D-Bus Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>pattern = &quot;^[a-fA-F0-9]{8}-[a-fA-F0-9]{4}-[a-fA-F0-9]{4}-[a-fA-F0-9]{4}-[a-fA-F0-9]{12}$&quot;</td>
<td>&quot;ay&quot; – ARRAY of BYTE</td>
</tr>
</tbody>
</table>

JSON strings with any other format value (e.g., date-time, uri, etc.) or pattern value not shown in Table 28 shall be treated the same as if the format and pattern attributes were absent, by simply mapping the value to a D-Bus string.

6.3.3.6 D-Bus Variants

If the introspection of an AllJoyn producer indicates a value in a request should be a D-Bus VARIANT, the translator should create such a variant and encode the incoming value as the variant’s payload as per the rules in the rest of this document. See Table 29.

<table>
<thead>
<tr>
<th>D-Bus Type</th>
<th>JSON Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;v&quot; – VARIANT</td>
<td>see clause 6.3.3.6</td>
</tr>
</tbody>
</table>

6.3.3.7 D-Bus Object Paths and Signatures

If the introspection of an AllJoyn producer indicates a value in a request should be a D-Bus Object Path or D-Bus Signature, the translator should perform a validity check in the incoming CBOR Text String. If the incoming data fails to pass this check, the message should be rejected. See Table 30.

<table>
<thead>
<tr>
<th>From D-Bus Type</th>
<th>To JSON Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;o&quot; – OBJECT_PATH</td>
<td>string</td>
</tr>
<tr>
<td>&quot;g&quot; – SIGNATURE</td>
<td></td>
</tr>
</tbody>
</table>
incoming CBOR payload may have changed the order of the fields, when compared to the D-Bus structure. When the version of AllJoyn implemented on the Bridged Device is less than v16.10.00, the translator shall follow the rule for translating D-Bus structures without the aid of introspection data.

6.3.3.9 Arrays and dictionaries

If the introspection of the AllJoyn interface indicates that the array is neither an ARRAY of BYTE ("ay") nor an ARRAY of VARIANT ("av") or that the dictionary is not mapping STRING to VARIANT ("a{sv}"), the translator shall apply the constraining or relaxing rules specified in other clauses. Similarly, if the OCF introspection indicates a homogeneous array type, the information about the array’s element type should be used as the D-Bus array type instead of VARIANT ("v").

6.3.3.10 Other JSON format attribute values

The JSON format attribute may include other custom attribute types. They are not known at this time, but it is expected that those types be handled by their type and representation alone.

6.3.3.11 Examples

Table 31 and Table 32 provide examples using introspection.

Table 31 – Mapping from AllJoyn using introspection

8.2 AllJoyn Object

8.2.1 Introduction

This resource is a collection of resources that were all derived from the same AllJoyn object.

8.2.2 Example URI

/example/AllJoynObject/

8.2.3 Resource type

The resource type (rt) is defined as: ['oic.r.alljoynobject', 'oic.wk.col'].

8.2.4 OpenAPI 2.0 definition

8.3 Secure Mode

8.3.1 Introduction

This resource describes a secure mode on/off feature (on/off).

A secureMode value of 'true' means that the feature is on, and any Bridged Server that cannot be
communicated with securely shall not have a corresponding Virtual OCF Server, and any Bridged
Client that cannot be communicated with securely shall not have a corresponding Virtual OCF
Client.

A secureMode value of 'false' means that the feature is off, any Bridged Server can have a
corresponding Virtual OCF Server, and any Bridged Client can have a corresponding Virtual OCF
Client.

8.3.2 Example URI

/example/SecureModeResURI

8.3.3 Resource type

The resource type (rt) is defined as: ['oic.r.securemode'].
